

Electricity

Presented by Oliver

Water power

Electricity can be made in many ways renewable and nonrenewable we will be focusing on both. But first we will start with a type of renewable energy water. Surprisingly we can make electricity using water. A dam is in place to block the water so it makes a reservoir. The water goes into the dam pushing around turbines this produces electricity at a huge scale this is a humongous help to the economy because hopefully water will never run out unlike fossil fuels that only reproduce every couple hundred years. A good thing

About this is that there is a lot of supply but it costs a

Lot to make a dam

Nuclear power

Nuclear power is generated by splitting uranium to create heat because uranium is a very hot atom. The steam that this creates turns generators to create power. There are good and bad things about this a good thing is it's cheap but uranium can be very unstable and there isn't much left.
